

Potential Energy Curves

Key Idea

Potential energy curves visualize the relationship between a particle's potential energy (U) and its position (x) under the influence of a conservative force. A graph that shows the change in potential energy U with x is called a potential energy graph or curve

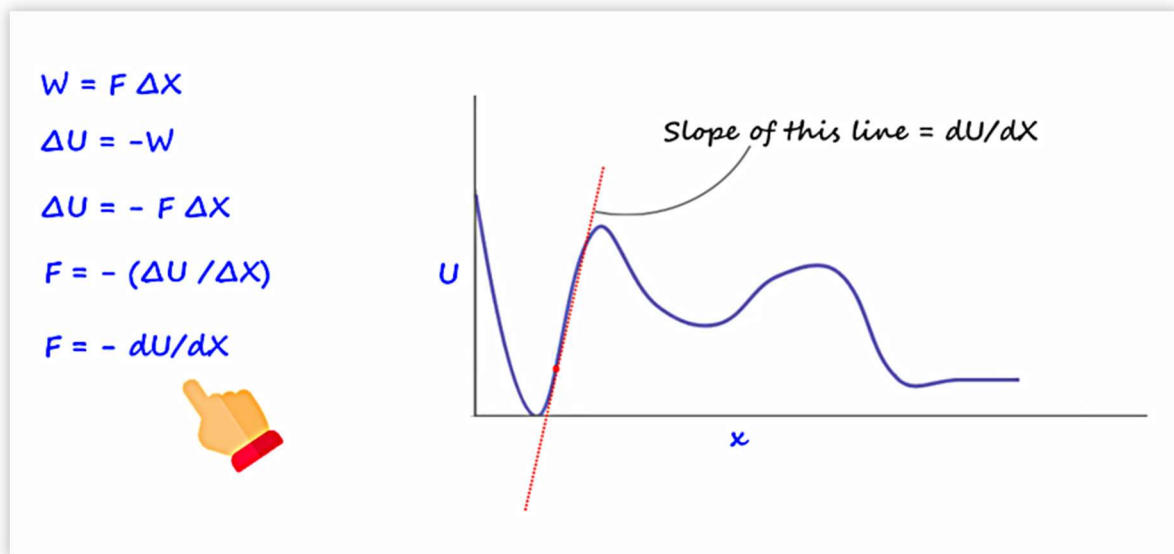

Equation Connecting Force, Potential Energy and Position

$$F = -dU/dx$$

Force equation

(1)

This formula implies that the force at any position x is equal to the negative of the rate of change of potential energy with respect to that position. *This rate of change is the slope of the curve at that position x*

Validating the equation ($F = -dU/dx$)

(a) Elastic Potential Energy and Hooke's Law

For a spring, the potential energy

$$U = 1/2 kx^2.$$

Differentiating with respect to x gives $dU/dx = kx$, which when substituted equation (1) yields

$$F = -kx.$$

This result confirms Hooke's law

(b) Gravitational Potential Energy

Consider the gravitational potential energy $U = mgx$.

Differentiating yields $dU/dx = mg$.

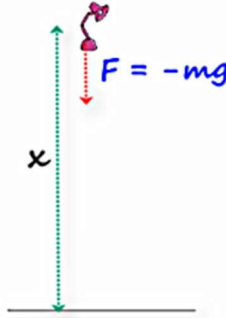

Leading to $F = -mg$ when applied to the force equation.

This example reinforces the relationship between force and potential energy.

$U = mgx$

$dU/dx = mg$

$F = -mg$

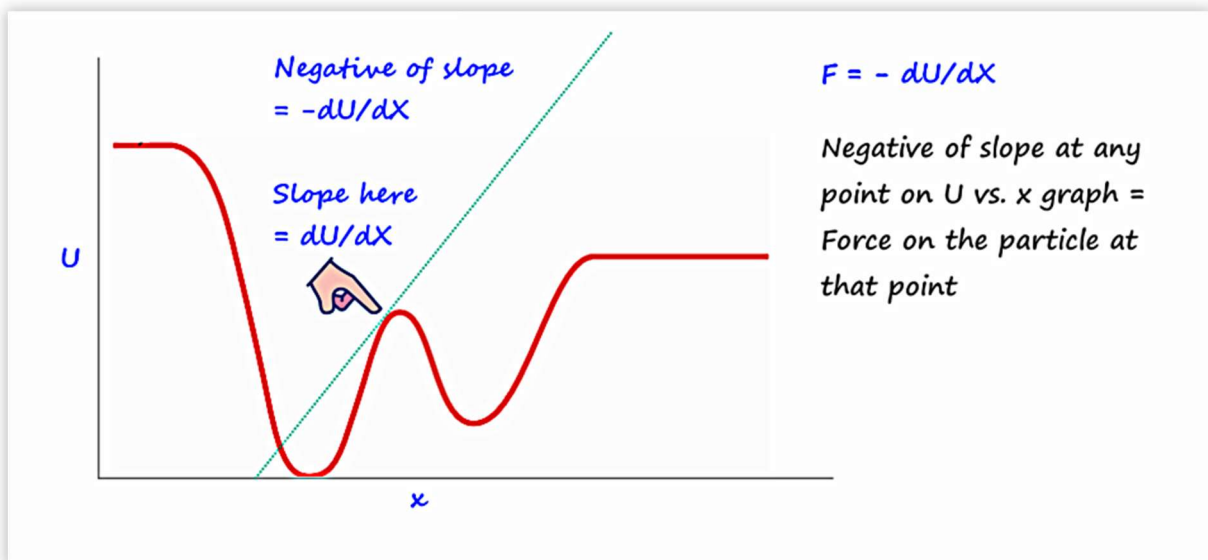

Analysing Potential Energy Graphs

The slope of the graph between potential energy U and position x is dU/dx .

$F = \text{Minus of Slope at the point } x \text{ under consideration, or}$

$$F = -dU/dx$$

Turning Points

A turning point is a point where a particle changes its direction of motion. Following are characteristics of turning points-

- Kinetic energy of particle becomes zero. Therefore, velocity drops to zero.
- A force exists on the particle but in a direction opposite the initial direction of motion.
- Mechanical Energy $E = U$ since $K = 0$ ($E = U + K$)

In the below U vs. x curve, x_1 is a turning point

Since the slope dU/dx at $x_1 < 0$, F becomes +ve.

(Remember F is negative of slope)

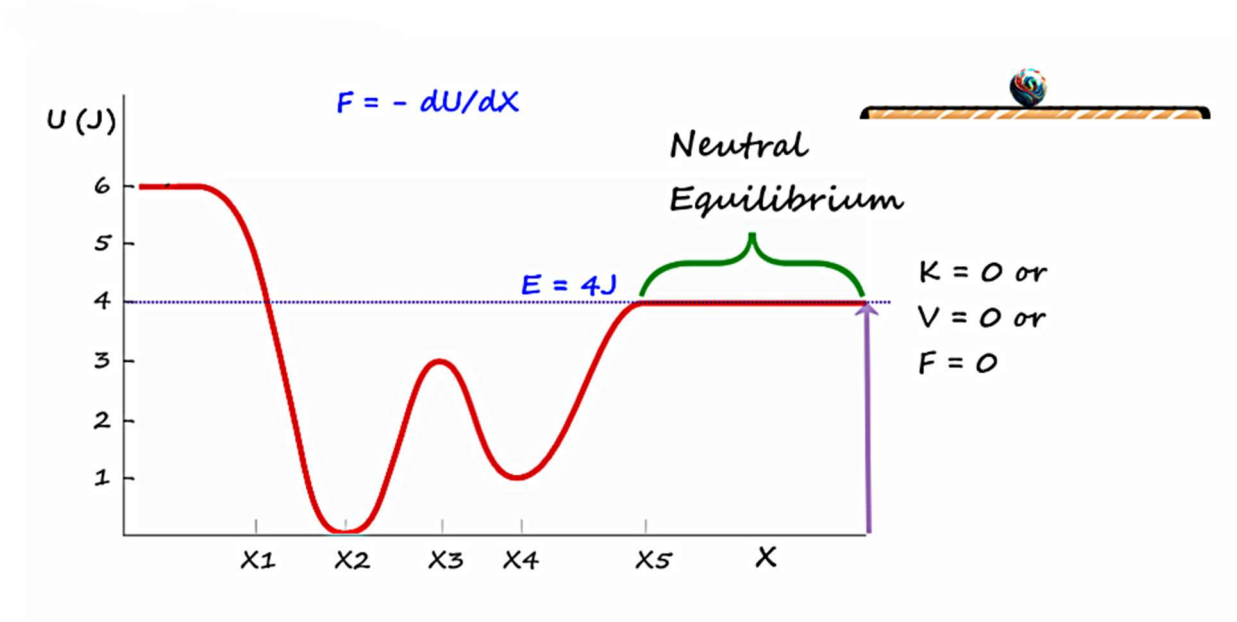

Equilibrium Points

There are three types of equilibrium points

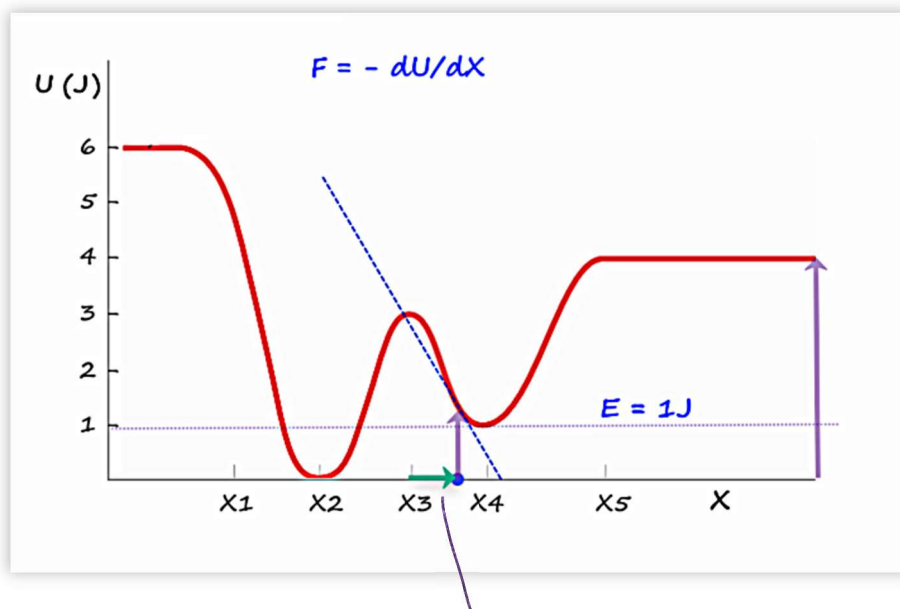

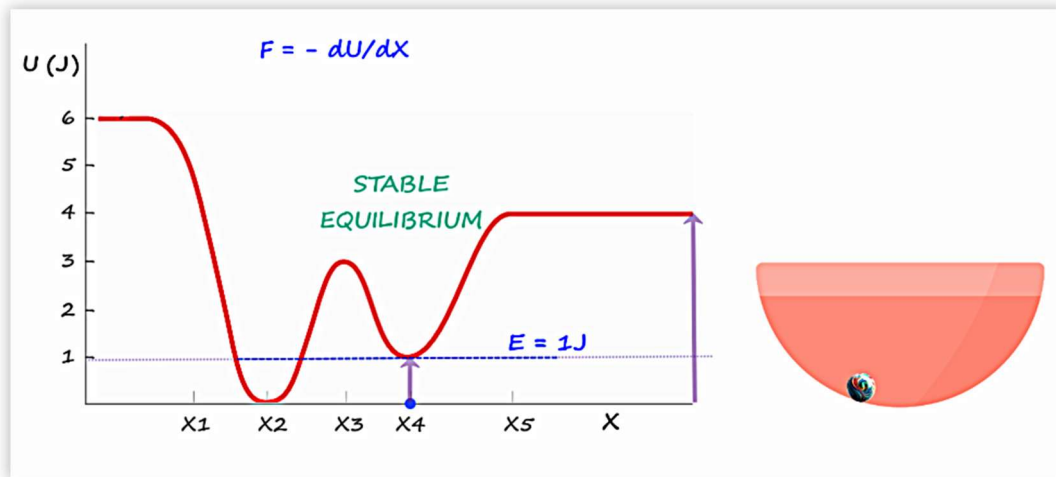

1. Neutral Equilibrium

- Slope at this point is zero
- Therefore, force on the particle is zero
- Therefore $KE = 0$ and velocity = 0
- Particle will remain stationary
- If you push it left or right, it will assume the new position. Notice along the flat line in the diagram below, even if you change position x , the slope remains zero that is force is also zero
- Example – marble put on a flat table

2. Stable Equilibrium (SE):

- Slope at the point of SE is zero (x_4 below)
- Therefore, force on the particle is zero
- $KE = 0$ and therefore velocity = 0
- A slight displacement of the particle results in a force that pushes the particle back towards the equilibrium point.
- Example: A marble at the bottom of a bowl.

If particle is moved to the left of x_4 , the slope changes and therefore a force is introduced in the direction of x_4 . This force restores the position back to x_4

3. Unstable Equilibrium (UE)

- Slope at the point of UE is zero (like x^3)
- Therefore, force on the particle is zero
- $KE = 0$ and therefore velocity = 0
- A slight displacement of the particle results in a force that pushes the particle further down in that direction
- Example: A marble at the top of a ball

If particle is pushed a little to the right from X_3 , the slope changes which means the force has been introduced and it will get pushed further in that direction
