## Torque

*The following questions are concept based and a recap of the lesson. For questions with higher level difficulty, watch videos in the course.*

**1. Which of the following correctly gives the torque  $\tau$  on a particle?**

- A.  $\tau = F \times r$
- B.  $\tau = r \times F$
- C.  $\tau = r \cdot F$
- D.  $\tau = F / r$

**Correct answer: B**

**Explanation:** By definition, torque is the cross product of the position vector  $r$  (from  $O$  to the point of force application) and the force  $F$ . The order matters:  $\tau = r \times F$ , not  $F \times r$

**2. Magnitude of torque is given by  $\tau = r F \sin \phi$ . What does multiplying  $\sin \phi$  to  $r F$  give?**

- A. Component of  $r$  parallel to  $F$
- B. Component of  $F$  parallel to  $r$
- C. Component of  $F$  perpendicular to  $r$
- D. Component of  $r$  perpendicular to  $F$

**Correct answer: C**

**Explanation:**  $\sin \phi$  isolates the component of  $F$  perpendicular to  $r$  ( $F_{\perp} = F \sin \phi$ ). Only this perpendicular component produces rotation.

**3. A force of 8 N acts at the end of a 0.25 m long lever arm, making an angle of  $60^\circ$  with the lever. What is the torque magnitude?**

- A. 1 N·m
- B.  $\sqrt{3}$  N·m

- C. 4 N·m
- D. 8 N·m

**Correct answer: B**

**Explanation:**  $\tau = r F \sin \phi = 0.25 \text{ m} \times 8 \text{ N} \times \sin 60^\circ = \sqrt{3} \text{ N}\cdot\text{m}$ .

**4. If  $\phi = 0^\circ$  between  $r$  and  $F$ , what is the torque?**

- A. Maximum
- B. Zero
- C. Equal to  $r F$
- D. Equal to  $r F \cos \phi$

**Correct answer: B**

**Explanation:**  $\sin 0^\circ = 0 \Rightarrow \tau = r F (0) = 0$ . When  $F$  is parallel to  $r$ , no rotational “push” is applied.

**5. Which of these is an alternative expression for torque using the moment arm  $r_\perp$ ?**

- A.  $\tau = r F \cos \phi$
- B.  $\tau = r_\perp F$
- C.  $\tau = r F \sin^2 \phi$
- D.  $\tau = r_\perp F \cos \phi$

**Correct answer: B**

**Explanation:** Moment arm  $r_\perp = r \sin \phi$  is the perpendicular distance from  $O$  to the line of action of  $F$ . Thus  $\tau = r_\perp F$ .

**6. At what angle  $\phi$  between  $r$  and  $F$  is the torque maximized?**

- A.  $0^\circ$
- B.  $45^\circ$
- C.  $90^\circ$
- D.  $180^\circ$

**Correct answer: C**

**Explanation:**  $\sin \phi$  is maximum (1) when  $\phi = 90^\circ$ , so  $\tau = r F$ .

**7. A particle lies at  $A(3 \text{ m}, 0)$  in the  $xy$  plane and a force  $F = (0, 4 \text{ N})$  acts on it. What is the direction of  $\tau$ ?**

- A. +x-axis
- B. -x-axis
- C. +z-axis
- D. -z-axis

**Correct answer: C**

**Explanation:**  $r = 3 \mathbf{i}$ ,  $F = 4 \mathbf{j}$ . Using  $r \times F$  and the right-hand rule ( $\mathbf{i} \rightarrow \mathbf{j}$ ),  $\tau$  points along  $+\mathbf{k}$  (the +z-axis).

**8. In the “perpendicular component” interpretation, torque can be seen as  $\tau = r F_{\perp}$ . What is  $F_{\perp}$ ?**

- A.  $F \cos \phi$
- B.  $F \sin \phi$
- C.  $F \tan \phi$
- D.  $F \cot \phi$

**Correct answer: B**

**Explanation:**  $F_{\perp}$  is the component of  $F$  perpendicular to  $r$ :  $F_{\perp} = F \sin \phi$ .

**9. When pushing open a door, why is it harder to push near the hinge than at the handle?**

- A.  $F$  is smaller near the hinge
- B.  $r_{\perp}$  is smaller near the hinge
- C.  $\phi$  is zero at the handle
- D.  $r$  is zero at the handle

**Correct answer: B**

**Explanation:** Near the hinge the moment arm  $r_{\perp}$  is small, so  $\tau = r_{\perp} F$  is small. Farther from the hinge (larger  $r_{\perp}$ ), torque increases, making it easier to open.

**10. Why must torque always be calculated as  $r \times F$  and never as  $F \times r$ ?**

- A.  $F \times r$  gives the same magnitude but wrong direction
- B.  $F \times r$  gives a scalar, not a vector
- C.  $r \times F$  follows the chosen right-hand convention for angular momentum and torque
- D.  $F \times r$  is undefined in vector algebra

**Correct answer: C**

**Explanation:** The cross product is anti-commutative:  $F \times r = -(r \times F)$ . Using  $r \times F$  ensures consistency with the right-hand rule and with angular momentum conventions.
