DATA TYPES (INT AND DOUBLE)

ERIC Y. CHOU, PH.D.

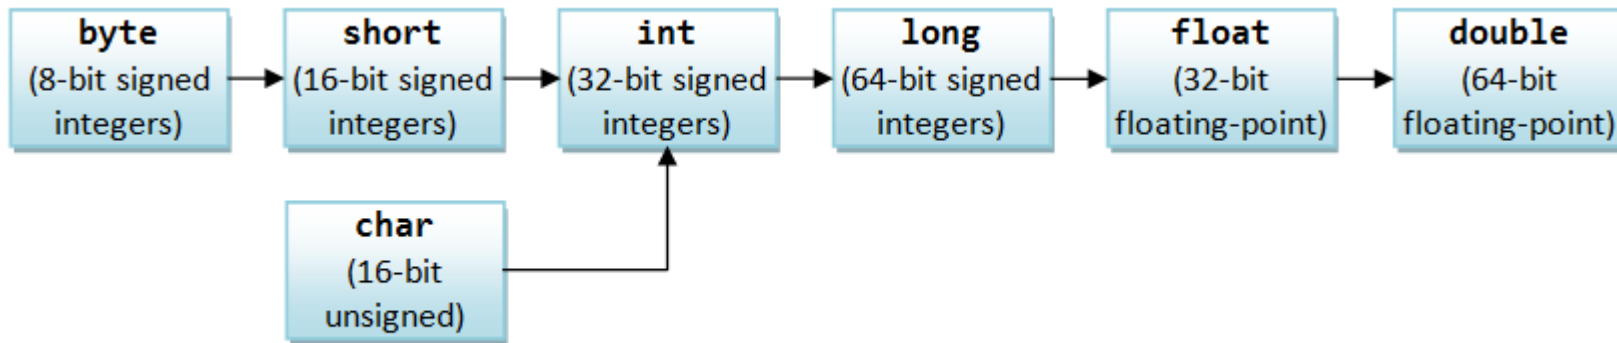

IEEE SENIOR MEMBER

# Numeric Data Types and Operations

Java has six numeric types for integers and floating-point numbers with operators +, -, \*, . and %

Name	Data	Range	Default Value	Size
byte	signed integer	[-128, 127]	0	8 bits
short	signed integer	[-32768, 32767]	0	16 bits
int	signed integer	[-2147483648, 2147483647]	0	32 bits
long	signed integer	[-9223372036854775808, 9223372036854775807]	0	64 bits
float	floating-point	MIN: $\pm 1.4E-45$ MAX: $\pm 3.4028235E+38$	0.0	32 bits
double	floating-point	MIN: $\pm 4.9E-324$ MAX: $\pm 1.7976931348623157E+308$	0.0	64 bits
char	Unicode	['\u0000', '\uFFFF']	'\u0000'	16 bits
boolean	logical value	{false, true}	false	$\geq 1$ bit

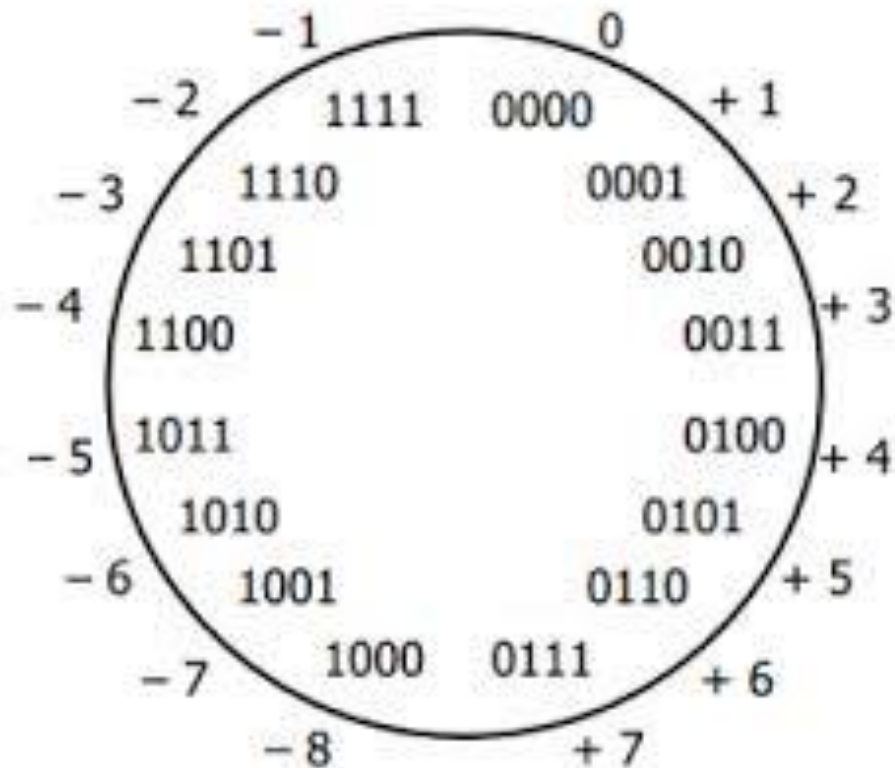

Orders of Implicit Type-Casting for Primitives

Integer.MIN\_VALUE  
Integer.MAX\_VALUE

# Two's Complement

Negative number is represented as two's complement.

For byte number's (8 bits):

$$-X = (2^8 - 1) - X + 1;$$

$$X + (-X) = X + (2^8 - X) = 2^8 = 0;$$

eg.

A = 0100 -> A's One's Complement = 1011 ->

A's Two's Complement -> 1100

The number  $2^8$  is a overflow for the byte format, because unsigned byte number range

from 0 to  $2^8 - 1 = 11111111$ .

Therefore, this method can work for computer.

# Finding 2's Complement

	-128	64	32	16	8	4	2	1	
$X$	0	1	0	0	1	1	1	1	<b>Number : 79 decimal</b>
$(2^8-1) - X$	1	0	1	1	0	0	0	0	<b>Flip the bits</b>
	0	0	0	0	0	0	0	1	<b>Add 1</b>
$NegX = (2^8-1) - X + 1$	1	0	1	1	0	0	0	1	<b>Number: -79 in 2's Complement format</b>

# Binary/Decimal Conversion

128	64	32	16	8	4	2	1
1	0	0	1	1	0	1	1
<hr/>							
128 + 0 + 0 + 16 + 8 + 0 + 2 + 1							
<b>= 155</b>							

wikihow

10011011

1	2 <sup>0</sup>	= 1
1	2 <sup>1</sup>	= 2
0	2 <sup>2</sup>	= 0
1	2 <sup>3</sup>	= 8
1	2 <sup>4</sup>	= 16
0	2 <sup>5</sup>	= 0
0	2 <sup>6</sup>	= 0
1	2 <sup>7</sup>	= 128
<hr/>		
Result = 155		

# Decimal to Binary

Handwritten-style conversion of 156 to binary:

$$\begin{array}{r} 2 \overline{)156} \\ 2 \overline{)78} \\ 2 \overline{)39} \\ 2 \overline{)19} \\ 2 \overline{)9} \\ 2 \overline{)4} \\ 2 \overline{)2} \\ 2 \overline{)1} \end{array}$$

Remainder:

0  
0  
1  
1  
1  
0  
0  
1

**$156_{10} = 10011100_2$**

wikihow

Divider	Dividend	Remainder
2	202	0
2	101	1
2	50	0
2	25	1
2	12	0
2	6	0
2	3	1
		1

# Java's special number rules (different from other languages)

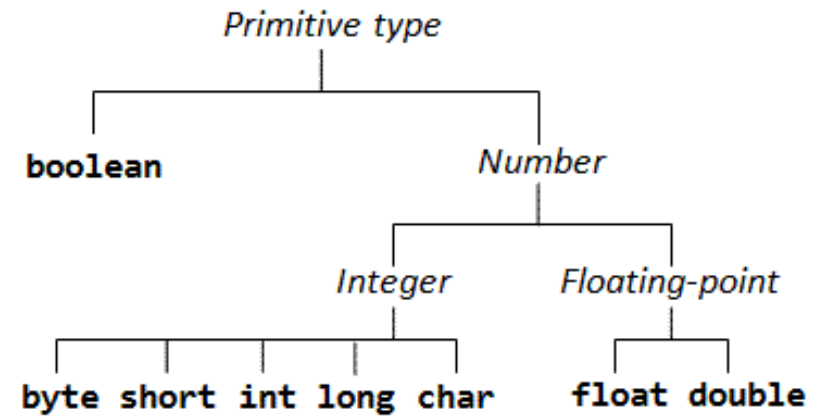

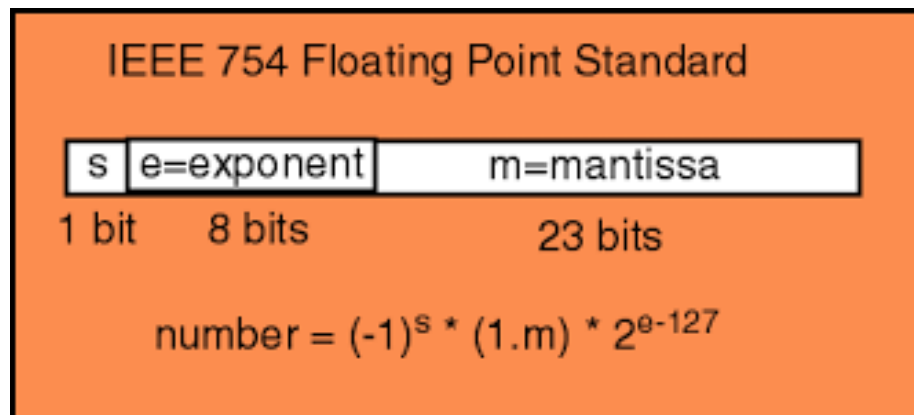

Java doesn't have unsigned number primitives.

unsigned number is seldom used.

If you need to use unsigned number, use **char** data type instead. Because char does not follow the number operation rules while **char** can still operate the **bit-wise** operations.

Java's char is 16 bit. (supporting Unicode: UTF-16)

IEEE 754 binary floating point representation. (Java's Float Standard)

Single precision (32-bit) form: (Bias = 127)

(1)sign (8) exponent (23) fraction

Double precision (64-bit) form: (Bias = 1023)

(1)sign (11) exponent (52) fraction

# Named Constants

A named constant is an identifier that represents a permanent value.

---

Syntax:

```
final <datatype> CONSTANTNAME = <value> ;
```

The word `final` is a Java reserved keyword for declaring a constant.

A constant in Java (or most of other language) is usually in all **UPPERCASE**.

Benefits for using constants:

- ❖ (1) you don't have to repeatedly type the same value over over again if it is used multiple times;
- ❖ (2) if you have to change the constant value, you need to change it only in a single location in the source code; and
- ❖ (3) a descriptive name for a constant makes the program easier to read.

# Named Constants

---

```
final datatype CONSTANTNAME = VALUE;
```

```
final double PI = 3.14159;
```

```
final int SIZE = 3;
```
